Monohybrid Cross, Dihybrid Cross, Sex-linked Inheritance 1, and Sex-linked Inheritance 2 Problem Sets and Tutorials

http://www.biology.arizona.edu/mendelian_genetics/mendelian_genetics.html

All answers must have some type of illustration supporting the logic of your answer

Click on Monohybrid Cross

Genetics is the study of heredity and variation in organisms. We begin with a study of the monohybrid cross, invented by Mendel. In a monohybrid cross, organisms differing in only one trait are crossed. Our objective is to understand the principles that govern inheritance in plants and animals, including humans, by solving problems related to the monohybrid cross.

3)

In Mendel's "Experiment 1," true-breeding pea plants with spherical seeds were crossed with true-breeding plants with dented seeds. (Spherical seeds are the dominant characteristic.) Mendel collected the seeds from this cross, grew F1-generation plants, let them self-pollinate to form a second generation, and analyzed the seeds of the resulting F2 generation. The results that he obtained, and that you would predict for this experiment are:

Click TUTORIAL

Click on PROBLEM 8

8)

A test cross is used to determine if the genotype of a plant with the dominant phenotype is homozygous or heterozygous. If the unknown is homozygous, all of the offspring of the test cross have the _____ phenotype. If the unknown is heterozygous, half of the offspring will have the _____ phenotype.

10)

A genetic cross of inbred snapdragons with red flowers with inbred snapdragons with white flowers resulted in F1-hybrid offspring that all had pink flowers. When the F1 plants were self-pollinated, the resulting F2-generation plants had a phenotypic ratio of 1 red: 2 pink: 1 white. The most likely explanation is:

11)

Human blood type is determined by codominant alleles. There are three different alleles, known as I^A, I^B, and i. The I^A and I^B alleles are co-dominant, and the i allele is recessive.

The possible human phenotypes for blood group are type A, type B, type AB, and type O. Type A and B individuals can be either homozygous (I^AI^A or I^BI^B, respectively), or heterozygous (I^Ai or I^Bi, respectively).

A woman with type A blood and a man with type B blood could potentially have offspring with which of the following blood types?

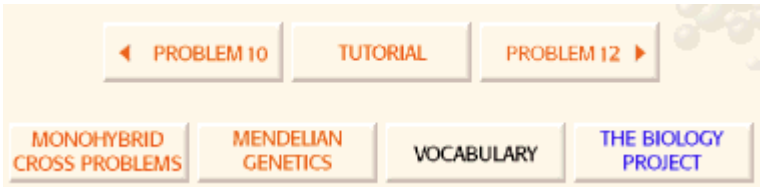
Click on PROBLEM 12



12)

Manx cats are heterozygous for a dominant mutation that results in no tails (or very short tails), large hind legs, and a distinctive gait. The mating of two Manx cats yields two Manx kittens for each normal, long-tailed kitten, rather than three-to-one as would be predicted from Mendelian genetics. Therefore, the mutation causing the Manx cat phenotype is likely a(n) _____ allele.

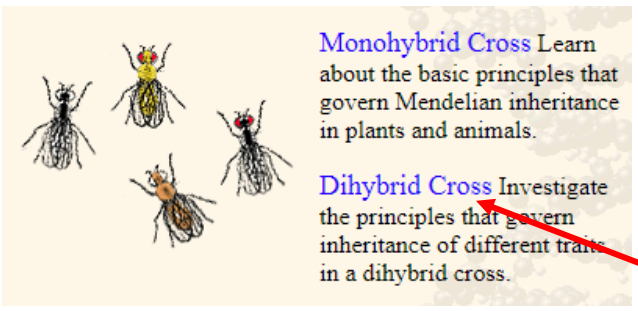
Click on Dihybrid Cross



A dihybrid cross involves a study of inheritance patterns for organisms differing in two traits. Mendel invented the dihybrid cross to determine if different traits of pea plants, such as flower color and seed shape, were inherited independently. Our objective is to understand the principles that govern inheritance of different traits in a dihybrid cross that led Mendel to propose that alleles of different genes are assorted independently of one another during the formation of gametes.

1)

A pea plant is heterozygous for both seed shape and seed color. S is the allele for the dominant, spherical shape characteristic; s is the allele for the recessive, dented shape characteristic. Y is the allele for the dominant, yellow color characteristic; y is the allele for the recessive, green color characteristic. What will be the distribution of these two alleles in this plant's gametes?

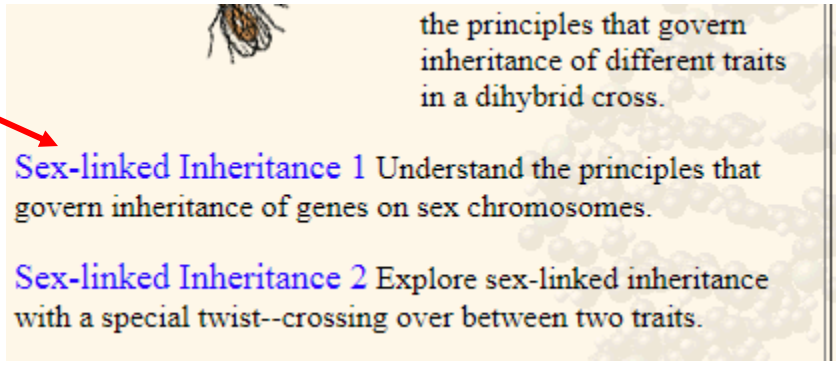
Click Sex-linked Inheritance 1



The study of inheritance of genes located on sex chromosomes was pioneered by T. H. Morgan and his students at the beginning of the 20th century. Although Morgan studied fruit flies, the same genetic principles apply to humans. Since males and females differ in their sex chromosomes, inheritance patterns for X-chromosome linked genes vary between the sexes. Our objective is to understand the principles that govern inheritance of genes on sex chromosomes.

1)

In a cross between a white-eyed female fruit fly and red-eyed male, what percent of the female offspring will have white eyes? (White eyes are X-linked, recessive)

Show your work!

Click TUTORIAL

Click on PROBLEM 2

2)

A female Drosophila of unknown genotype was crossed with a white-eyed male fly, of genotype X^wY (w = white eye allele is recessive, w+= red-eye allele is dominant.) Half of the male and half of the female offspring were red-eyed, and half of the male and half of the female offspring were white-eyed. What was the genotype of the female fly?

Show your work!

Click TUTORIAL

Click on PROBLEM 3

3)

In a cross between a pure bred, red-eyed female fruit fly and a white-eyed male, what percent of the male offspring will have white eyes? (white eyes are **X**-linked, recessive)

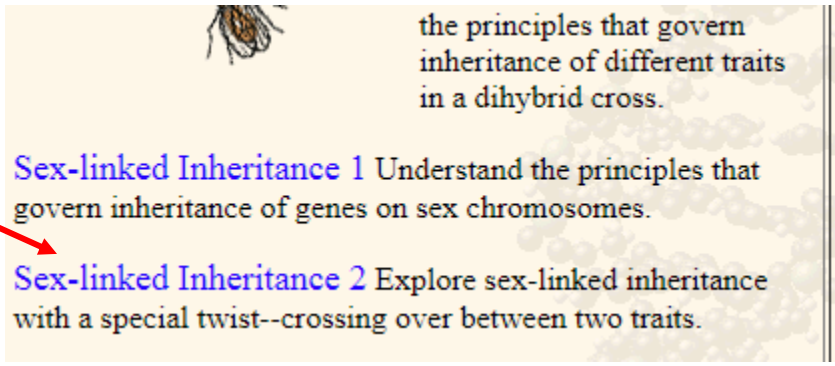
Click on Sex-linked Inheritance 2



A. H. Sturtevant, a student of T. H. Morgan, published a paper in 1913 entitled "The Linear Arrangement of Six Sex-Linked Factors in Drosophila, as Shown by Their Mode of Association" (J. Exptl. Zoology, volume 14, pages 43-59.) Sturtevant provided experimental evidence that genes were organized in a linear fashion on chromosomes by quantitiative analysis of the frequency of crossing-over between two traits carried on the **X**-chromosome of the fruit fly. This series of questions demonstrates the type of genetic cross used by Sturtevant in this study.

1)

The alleles for eye color and for body color are on the **X** chromosome of Drosophila, but not on the **Y**. Red eye color (w+) is dominant to white eye color (w), and tan body color (y+) is dominant to yellow body color (y).

What is the genotype of a yellow-bodied, red-eyed female who is homozygous for eye color?

Show your work!

Click TUTORIAL

Click on PROBLEM 2

2)

The alleles for eye color and for body color are on the **X** chromosome of Drosophila, but not on the **Y**. Red eye color (w+) is dominant to white eye color (w), and tan body color (y+) is dominant to yellow body color (y).

What is the genotype of a tan-bodied, white-eyed male?

Show your work!

Click TUTORIAL

Click on PROBLEM 3

3)

What offspring would you expect from a cross between the female Drosophila described in problem 1 (red eyes and a yellow body, homozygous recessive for the yellow body color allele and homozygous dominant for the eye color allele) and the male described in problem 2 (hemizygous for both the recessive (white) eye color allele and dominant (tan) body color allele?)

A reminder that the alleles for eye color and for body color are on the **X**chromosome of Drosophila, but not on the **Y**. Red eye color (w+) is dominant to white eye color (w), and tan body color (y+) is dominant to yellow body color (y).
